

5 Output Ultra Low Jitter LVCMOS Fan out Buffer

Description

The SiT92113 is a 5 output low-jitter clock, fan-out buffer, intended to be used in low jitter, high frequency clock/data distribution. The low impedance LVCMOS outputs are designed to drive 50 Ω series or parallel terminated transmission lines.

The buffer can choose a clock input from primary, secondary or crystal source. The primary and secondary clock sources can be single ended or fully differential. The selected clock is distributed to 5 LVCMOS output drivers.

The SiT92113 operates from a 3.3 V/2.5 V core supply and 3.3 V/2.5 V output supply. The core supply and output supply are independent of each other and no supply sequencing is required.

Applications

- Carrier Ethernet
- 5G Wireless Infrastructure, Small Cells

Nomenclature:

SiT92113: 24 pin, 4 mm x 4 mm, QFN

Features

- Additive jitter performance of 50 fs RMS.
- Typical output skew between clock outputs is 30 ps
- Level translation with core supply voltage of 3.3 V/2.5 V and 3.3 V/2.5 V / 1.8 V/ 1.5 V output supply for LVCMOS output drivers.
- The device inputs consists of primary, secondary and crystal inputs.
- The inputs are selected by programming input select pins of SiT92113. The input clock receiver in SiT92113 can accept LVPECL, LVDS, LVCMOS, SSTL, HCSL and OSC waveforms.
- Crystal frequencies from 8 MHz to 50 MHz are supported.
- Crystal input can be over driven with frequency up to 250 MHz in crystal bypass mode
- SiT92113 buffer is available in a 24-pin, 4 mm x 4 mm QFN package.

Table 1 Absolute Maximum Ratings

Parameter	Conditions	Symbol	Min	Typ	Max	Units
Core Supply Voltage		V_{DD}	-0.5		3.6	V
Output Supply Voltage		V_{DDO}	-0.5		3.6	V
Input voltage, All Inputs, except OSC_IN		V_{IN}	-0.3		$V_{DD}+0.3$	V
OSC_IN		V_{IN}	-0.3		1.5	V
Storage temperature		T_{STG}	-55		150	°C
Junction Temperature		T_J			125	°C
Moisutre Saturation Level		MSL		3		

Notes:

- Exceeding maximum ratings may shorten the useful life of the device.
- Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or at any other conditions beyond those indicated under the DC Electrical Characteristics is not implied. Exposure to Absolute-Maximum-Rated conditions for extended periods may affect device reliability or cause permanent device damage.

Notes:

1. Inverting differential input clock pin biased at VDD/2
2. Input common mode defined as VIH.
3. Specification is guaranteed by characterization and is not tested in production
4. If the input clock is initially absent when the chip is just powered up, it will take at least 2 falling edge of clock cycles for the output to appear. Therefore, the buffer level translates DC only after it sees two consecutive falling edge of input clock
5. Output duty cycle equals input duty cycle. ATE measurement done with 80% on time and 20% off time waveform to make sure that output duty cycle is equal to input duty cycle even with skewed input duty cycle.

Functional Description

Functional Block Diagram

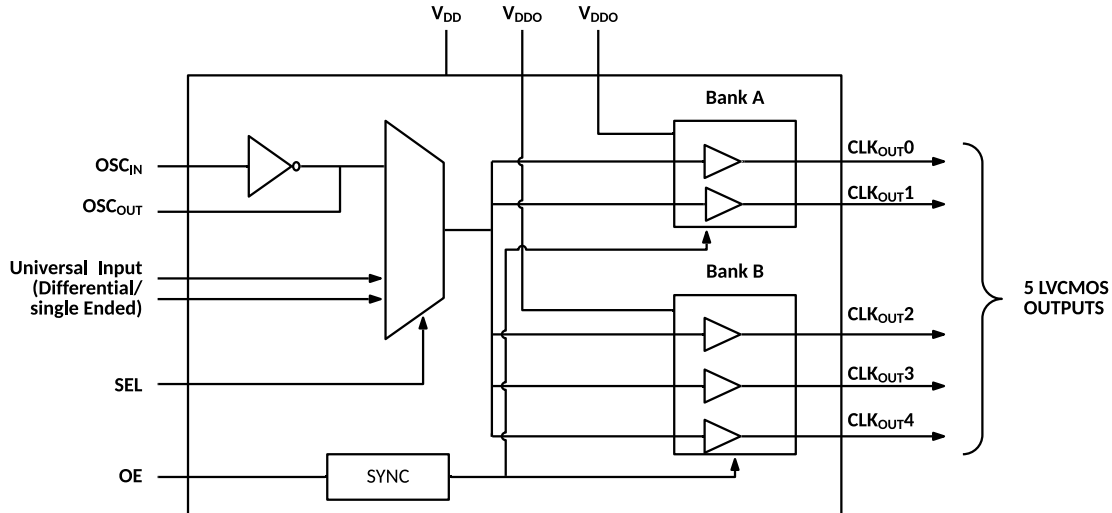

Figure 3 Functional Block Diagram

The SiT92113 is a 5-output differential clock fan out buffer with low additive jitter that can operate up to 250 MHz. It features a 2:1 input multiplexer with either a differential/single ended input clock or crystal oscillator input and five LVCMOS outputs. The input selection and output buffer modes are controlled via pin strapping. The device is offered in a 24-pin QFN package.

VDD and VDDO Power Supplies

The SiT92113 has separate 3.3 V/2.5 V core (VDD) and 3.3 V/2.5 V/1.8 V/1.5 V output power supply (VDDO). Output supply operation at 2.5 V/1.8 V/1.5 V enables lower power consumption and output-level compatibility with 2.5 V/1.8 V/1.5 V receiver devices. The output levels LVCMOS (VOH) is referenced to its respective VDDO supply.

Clock Inputs

The input clock can be selected from primary universal clock input, secondary universal clock input, or Xin. Clock input selection is controlled using the SEL[0] inputs as shown in [Table 10](#)

Table 10 Input Clock Selection

SEL	Selected Clock
0	CLK
1	Crystal Or Crystal bypass AC coupled mode

Clock States (Input vs Output States)

Table 11 Input vs Output Stages

State of Selected Clock input	Output State
Inputs are floating	Logic Low
Inputs are logic low	Logic Low
Inputs are logic high	Logic High

Output Enable

Pulling OE to LOW, forces the outputs to the high-impedance state after the four falling edge of the input signal. The outputs remain in the high-impedance state as long as OE is LOW. The OE signal is internally synchronized to the selected input clock. This allows disabling the output clock at the falling edge of input clock in a glitch free manner.

When OE goes from low to high, the output clock is enabled within a time delay t_d , where t_d is given by the following equation.

$$t_{d,refout_en} = 0.5n + 4 * T_{in}$$

T_{in} is the time period of the input clock.

Table 12 OE Functionality

Application Information

Driving the Clock Inputs

The SiT92113 has two universal clock inputs (CLK0/nCLK0 and CLK1/nCLK1). SiT92113 can accept 3.3 V/2.5 V LVPECL, LVDS, CML, SSTL, and other differential and single-ended signals that meet input common mode, slew rate and swing requirements specified in the Electrical Characteristics. The SiT92113 supports a wide common mode voltage range and input signal swing.

To achieve the best possible phase noise and jitter performance, it is mandatory for the input to have high slew rate of 2 V/ns (differential) or higher. Driving the input with a lower slew rate will degrade the noise floor and jitter.

It is recommended to drive the input signal differentially for better slew rate and jitter. The user can also drive a single ended clock. If the user is driving the single ended clock signal on say CLK0, then nCLK0 pin need to be connected to a 0.1 uF capacitor on the PCB.

Driving Clock Inputs with LVCMOS Driver (AC coupled)

Figure 6 shows how a differential input can be wired to accept LVCMOS single ended levels in AC coupled mode. The bypass capacitor (C1) is used to help filter noise on the DC bias on the inverting pin of the clock input. This bypass should be located as close to the input pin as possible. Two

resistors R_{T1} and R_{T2} set the common mode voltage at the output of the LVCMOS driver to $V_{DD}/2$. This prevents average DC leakage current from the LVCMOS driver and avoids unnecessary power dissipation.

For example, if the input clock is driven from a single-ended 2.5 V LVCMOS driver and the DC offset (or swing center) of this signal is 1.25 V, the R_{T1} and R_{T2} values should be adjusted to set the V_1 at 1.25 V. This configuration requires that the sum of the output impedance of the driver (R_o) and the series resistance (R_s) equals the transmission line impedance. In addition, matched termination at the input will attenuate the signal in half. This can be done in the following way. First, R_{T1} and R_{T2} in parallel should equal the transmission line impedance. For most 50 Ω applications, R_{T1} and R_{T2} can be 100 Ω .

$$Z_o = R_o + R_s = 50 \Omega$$

$$\frac{R_{T1} * R_{T2}}{R_{T1} + R_{T2}} = 50 \Omega$$

$$\frac{V_{DD} * R_{T2}}{R_{T1} + R_{T2}} = \frac{V_{DD}}{2}$$

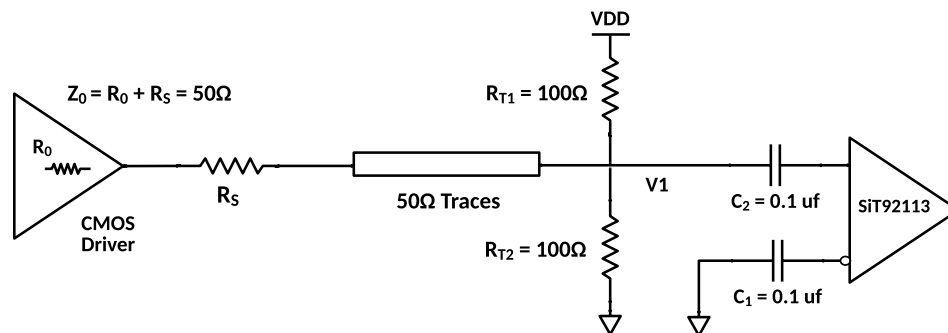

Figure 6 AC coupling LVCMOS clock to SiT92113

The inverting differential input can be connected to a 0.1 uF bypass capacitor. This pin is biased internally to a voltage close to $V_{DD}/2$.

Another variant of the AC coupling of LVCMOS input clock is shown in Figure 7. We use single termination resistor of

50 Ω to ground. A 0.1 uF AC coupling capacitor is connected in series with the LVCMOS clock source to prevent DC leakage current.

$$Z_o = R_o + R_s = 50 \Omega$$

Figure 7 AC coupling of LVCMOS clock with single 50 Ω resistor termination to ground

Driving Clock Inputs with LVCMOS Driver (DC coupled)

Figure 8 shows how a differential input can be wired to accept LVCMOS single ended clock signals in DC coupled mode. The reference voltage $V1 = VDD/2$ is generated by the bias resistors $RS1$ and $RS2$. The bypass capacitor ($C1$) is used to help filter noise on the DC bias. This bias circuit should be located as close to the input pin as possible. The ratio of $RS1$ and $RS2$ might need to be adjusted to position the bias voltage $V2$ in the center of the input voltage swing. Typical values of bias circuit resistance are $RS1 = 1\text{ K}\Omega$ and $RS2 = 1\text{ K}\Omega$

$$Z_o = R_o + R_s = 50 \Omega$$

$$\frac{VDD * R_{S2}}{R_{S1} + R_{S2}} = \frac{VDD}{2}$$

$$\frac{R_{T1} * R_{T2}}{R_{T1} + R_{T2}} = 50 \Omega$$

$$\frac{VDD * R_{T2}}{R_{T1} + R_{T2}} = \frac{VDD}{2}$$

Figure 8 DC coupling of LVCMOS clock to SiT92113 – configuration 1

For example, if the input clock is driven from a single-ended 2.5 V LVCMOS driver and the DC offset (or swing center) of this signal is 1.25 V, the $RS1$ and $RS2$ values should be adjusted to set the $V2$ at 1.25 V. The values below are for

when both the single ended swing and VDD are at the same voltage.

This configuration requires that the sum of the output impedance of the driver (R_o) and the series resistance (R_s) equals the transmission line impedance. In addition,

matched termination at the input will attenuate the signal in half. This can be done in one of two ways. First, R_{T1} and R_{T2} in parallel should equal the transmission line impedance. For most 50 Ω applications, R_{T1} and R_{T2} can be 100 Ω . The values of the resistors can be increased to reduce the loading for slower and weaker LVCMOS driver.

Figure 9 shows a second input clock configuration where R_{T1} , R_{T2} are removed and replaced with a 50 Ω termination resistor R_T to ground. It is possible that LVCMOS driver (or clock source) may not be able to drive 50 Ω load in DC coupled mode. The user can use series RC termination to overcome this limitation. The design equations for the input clock configuration shown in Figure 9 is given below.

$$Z_o = R_o + R_s = 50 \Omega$$

$$\frac{VDD * R_{s2}}{R_{s1} + R_{s2}} = \frac{V_{pp}}{2}$$

The LVCMOS single ended clock input with series RC termination near the buffer is shown in Figure 10. There is a single termination resistor R_T which is connected to ground through a capacitor C_{AC} . The value of series capacitor is given by a formula.

$$C_{AC} \geq \frac{3T_D}{50\Omega} \quad T_D \text{ is the transmission line delay}$$

Figure 9 DC coupled LVCMOS input clock configuration – configuration 2

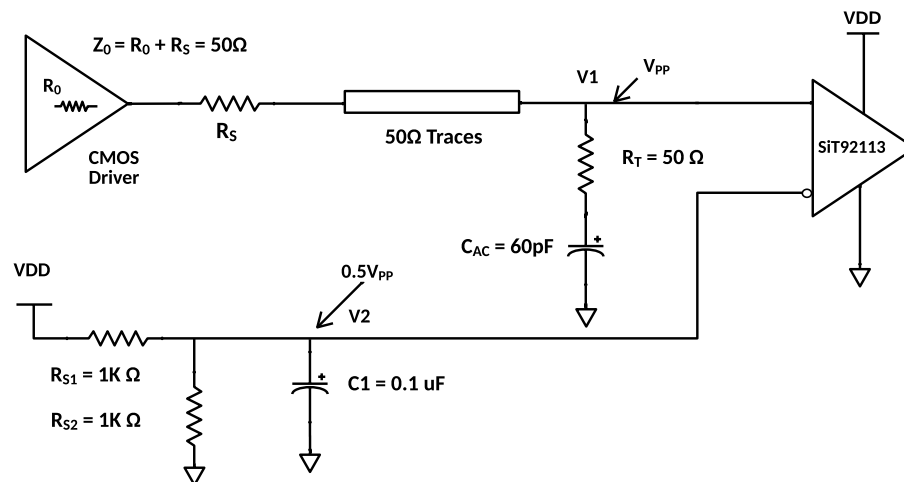

Figure 10 DC coupled LVCMOS input clock with series RC termination – configuration 3

For low frequencies we can direct couple the LVCMOS clock to SiT92113 input clock pin as shown in [Figure 11](#)

Figure 11: Direct coupling of LVCMOS clock to SiT92113

Driving OSC_IN with LVCMOS Driver (AC coupled)

The crystal input OSC_IN can be overdriven with single ended clock (LVCMOS driver or one side of a differential driver). The peak swing at OSC_IN should be limited to 1.5 V. The OSC_OUT pin, in this case can be floating. The SEL should be 1. The maximum voltage at OSC_IN should not exceed 1.5 V and minimum voltage should not go below -0.3 V. The slew rate at OSC_IN should be greater than 0.2 V/ns.

For 3.3 V LVCMOS inputs, the amplitude must be reduced from full swing to at least half the swing in order to prevent signal interference with the power rail and to reduce internal noise. [Figure 12](#) shows an example of the interface diagram for a high speed 3.3 V LVCMOS driver. This configuration requires that the sum of the output impedance of the driver (Ro) and the series resistance (Rs) equals the transmission line impedance. In addition, matched termination at the crystal input will attenuate the signal in half. This can be

done in one of two ways. First, RT1 and RT2 in parallel should equal the transmission line impedance. For most 50 Ω applications, RT1 and RT2 can be 100 Ω.

$$Z_o = R_o + R_s = 50 \text{ Ohm}$$

$$\frac{R_{T1} * R_{T2}}{R_{T1} + R_{T2}} = 50 \text{ Ohm}$$

$$\frac{VDD * R_{T2}}{R_{T1} + R_{T2}} = \frac{VDD}{2}$$

For both the AC coupled configurations, the maximum peak to peak swing before the ac coupling capacitor is 1.65 V. The maximum DC bias voltage of OSC_IN is 0.675V. Therefore the maximum swing at the OSC_IN pin is given by the equation given below.

$$V_{swing, pk, XTAL_IN} = 0.675 + 0.5 * 1.65 = 1.5V$$

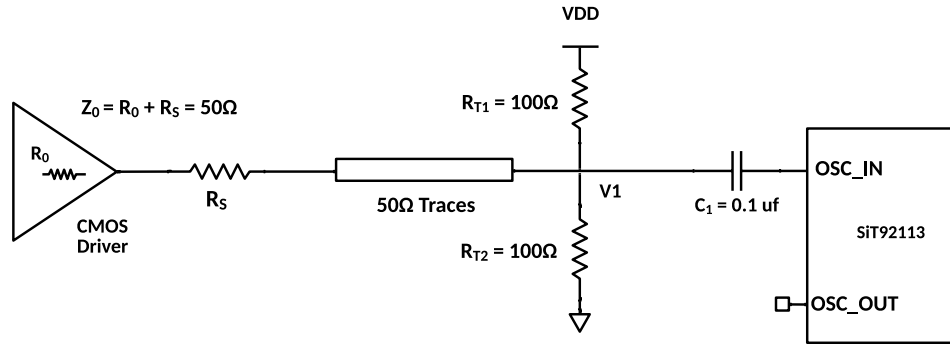

Figure 12 Single ended LVCMOS input – configuration 1, AC coupling to crystal input

Figure 13 shows a second input clock configuration where R_{T1} , R_{T2} are removed and replaced with a 50 Ω termination resistor R_T to ground. A 0.1 μF is in series with the CMOS driver to prevent any DC leakage current.

Figure 13 Single ended LVCMOS input – configuration 2, AC coupling to crystal input

LVDS (DC coupled)

Terminate with a differential 100 Ω as close to the receiver as possible. This is shown in Figure 14

Figure 14 Termination scheme for DC coupled LVDS

HCSL (DC coupled)

Termination resistor is 50 Ω to ground, close to the output driver. A series resistance R_s is sometimes used to limit the overshoot during fast transients. The termination scheme is shown in [Figure 15](#)

Figure 15 Termination scheme for DC coupled HCSL

LVPECL (DC coupled)

For DC coupled operation, the 50 Ω termination resistors are placed close to the receiver. The termination resistors are biased with a voltage source V_{TT} .

$$V_{TT} = V_{DDO} - 2V.$$

This termination scheme is shown in [Figure 16](#). Alternatively, the user can also implement a Thevenin equivalent of V_{TT} using a resistor divider. This scheme and the values of the resistors in the resistor divider are given in [Figure 17](#).

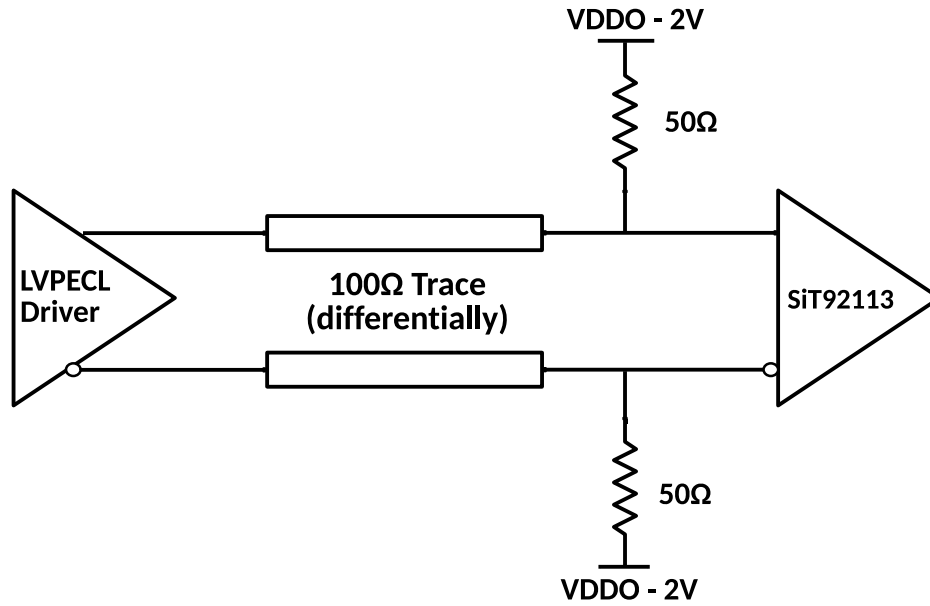

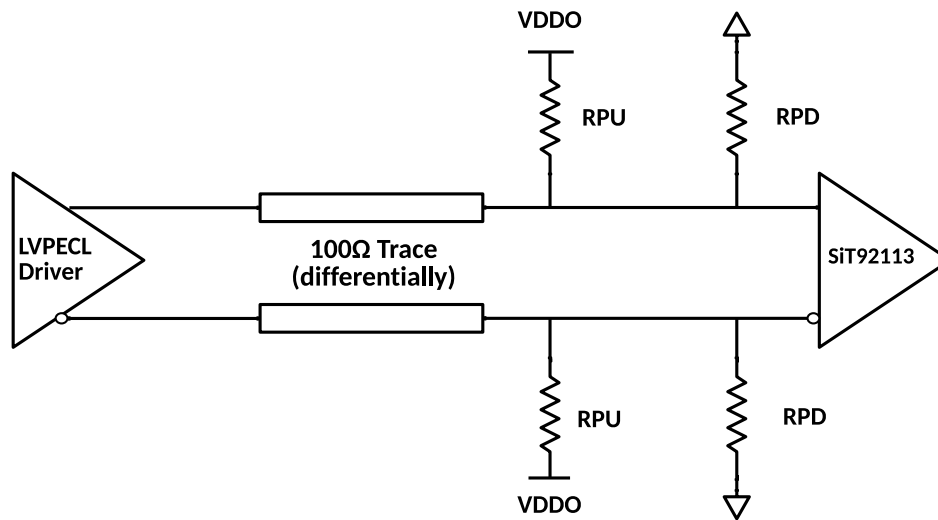

Figure 16 Termination scheme for DC coupled LVPECL

V_{DDO}	RPU	RPD	VTT
3.3 V	120 Ω	82 Ω	~ 1.3 V
2.5 V	250 Ω	62.5 Ω	0.5 V

Figure 17 Termination scheme for DC coupled LVPECL, Thevenin equivalent

The design equations for the LVPECL Thevenin equivalent termination are given below.

$$\frac{R_{PD} * R_{PU}}{R_{PD} + R_{PU}} = 50\Omega$$

$$\frac{R_{PD} * VDDO}{R_{PD} + R_{PU}} = VDDO - 2V$$

SSTL (DC coupled)

The SSTL input clock configuration is shown in [Figure 18](#). The transmission line impedance is 60 Ω in the application example given. Therefore, we use two 120 Ω resistors from

VDDO to ground for biasing the clock input pins. The effective termination impedance in this case is 60 Ω.

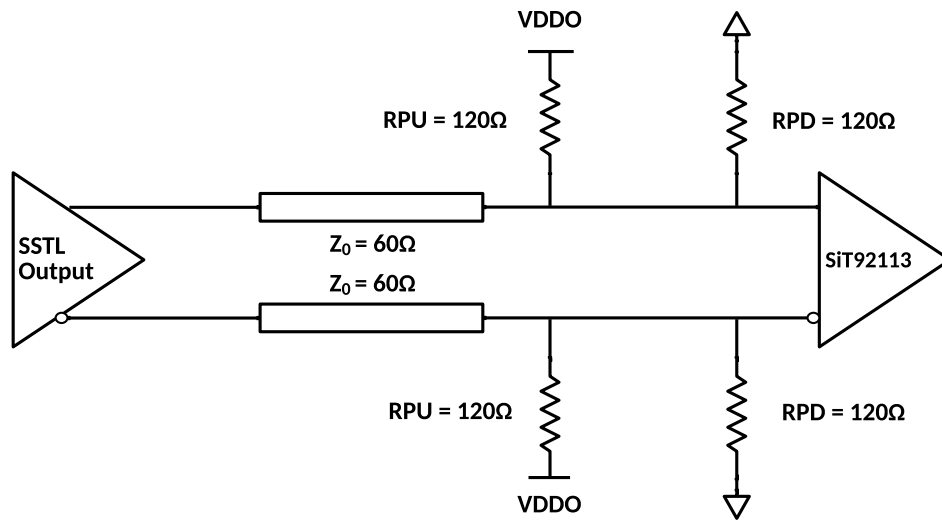

Figure 18 Example of input clock termination for SSTL clock.

LVDS (AC coupled)

The load termination resistor should be placed before the AC coupling capacitors. The load termination resistor and

the AC coupling capacitors should be placed close to the receiver. The termination scheme is shown in [Figure 19](#).

Figure 19 Termination scheme for AC coupled LVDS

LVPECL (AC coupled)

The LVPECL should have a DC path to ground. So, the user must place a resistance R_T , close to the output driver. The

LVPECL AC coupling and Thevenin equivalent VTT termination scheme is shown in Figure 20.

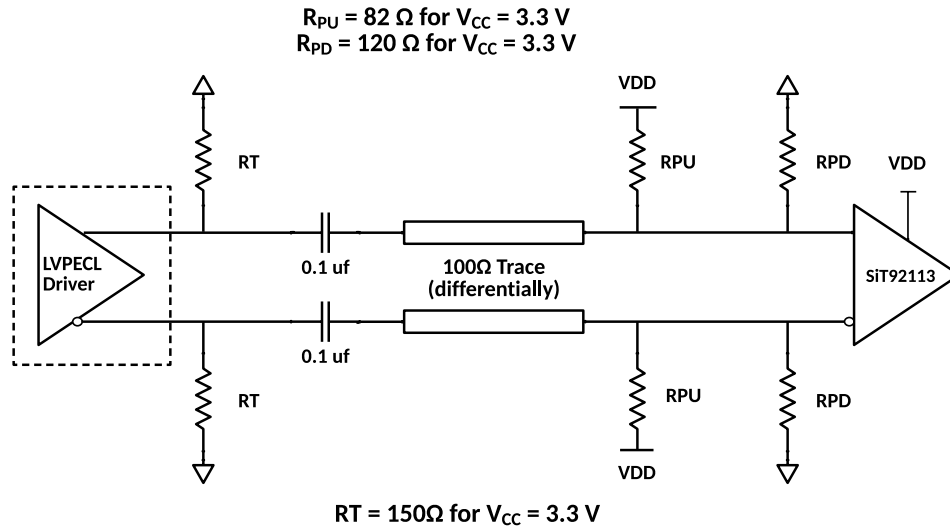

Figure 20 Termination scheme for AC coupled LVPECL, Thevenin Equivalent

The pull up resistance R_{PU} and pull down resistance R_{PD} sets the input common mode voltage for SiT92113. The value of the input common mode voltage can be estimated by the equation given below

$$V_{ICM} = \frac{VDD * R_{PD}}{R_{PU} + R_{PD}} = \frac{3.3 * 120}{120 + 82} = 1.961V$$

The differential input common mode specification of SiT92113 (from data sheet) is $VDD - 1.1 = 2.2 V$, therefore the input common mode set by LVPECL AC coupled

termination meets the SiT92113 input common mode specification.

The LVPECL driver chip has resistance R_T providing DC path for the output driver current in the LVPECL driver. The effective load impedance at the input side of SiT92113 (receiver side) is formed by parallel combination of R_{PU} , R_{PD} .

The effective termination resistor value is given by the equation below

$$R_{termination} = \frac{R_{PU} * R_{PD}}{R_{PU} + R_{PD}} = \frac{120 * 82}{120 + 82} = 48.7 \Omega$$

Termination of Output Driver of SiT92113 for Various Load Configurations

SiT92113 Output ODR Termination for AC Coupled mode

AC coupling of SiT92113 LVCMOS output driver is shown in Figure 21. We use single termination resistor of 50 Ω s to ground. A 0.1 uF AC coupling capacitor is connected in series with the LVCMOS clock source to prevent DC leakage current. The receiver side is terminated with a single 50 Ω resistance to ground. The clock signal is then

AC coupled to the receiver, in this example. C1 is a bypass capacitor that is used to suppress noise on the inverting differential input of the receiver.

$$Z_o = R_o + R_s = 50 \Omega$$

Figure 21 AC coupling of LVCMOS clock with single 50 Ω resistor termination to ground

SiT92113 Output ODR Termination for DC Coupled mode

Figure 22 shows how SiT92113 LVCMOS output drive can be terminated to send clock signals in DC coupled mode. The reference voltage $V1 = VDD/2$ is generated by the bias resistors R_{S1} and R_{S2} . The bypass capacitor ($C1$) is used to help filter noise on the DC bias. This bias circuit should be located as close to the input pin as possible. The ratio of R_{S1} and R_{S2} might need to be adjusted to position the bias voltage $V2$ in the center of the input voltage swing.

$$Z_o = R_o + R_s = 50 \Omega$$

$$\frac{VDD * R_{S2}}{R_{S1} + R_{S2}} = \frac{VDD}{2}$$

Typical value of $R_{S1} = R_{S2} = 1K\Omega$

$$\frac{R_{T1} * R_{T2}}{R_{T1} + R_{T2}} = 50 \text{ Ohm,}$$

Typical value of $R_{T1} = R_{T2} = 100\Omega$

$$\frac{VDD * R_{T2}}{R_{T1} + R_{T2}} = \frac{VDD}{2}$$

Figure 22 DC coupling of LVCMOS output clock termination – configuration 1

For example, if the SiT92113 supply is 2.5 V then the DC offset (or swing center) of this signal is 1.25 V, the R_{S1} and R_{S2} values should be adjusted to set the V2 at 1.25 V. The values below are for when both the single ended swing and VDD are at the same voltage.

This configuration requires that the sum of the output impedance of the driver (R_o) and the series resistance (R_s) equals the transmission line impedance. In addition, matched termination at the input will attenuate the signal in half. This can be done in one of two ways. First, R_{T1} and R_{T2} in parallel should equal the transmission line impedance. For most 50 Ω applications, R_{T1} and R_{T2} can be 100 Ω . The values of the resistors can be increased to reduce the loading for slower and weaker LVC MOS driver.

Figure 23 shows a second input clock configuration where R_{T1} , R_{T2} are removed and replaced with a 50 Ω termination resistor R_T to ground. There will be DC leakage current from SiT92113, for the output termination shown in Figure 23

The user can use series RC termination to overcome this limitation. The design equations for the input clock configuration shown in Figure 23

$$Z_o = R_o + R_s = 50 \text{ Ohm}$$

$$\frac{VDD * R_{s2}}{R_{s1} + R_{s2}} = \frac{V_{pp}}{2} = \frac{VDD}{4},$$

$$\text{Typical value of } R_{s1} = 3K\Omega, R_{s2} = 1K\Omega$$

The SiT92113 LVC MOS output driver termination with series RC termination near the buffer is shown in Figure 24. There is a single termination resistor R_T which is connected to ground through a capacitor C_{AC} . The value of series capacitor is given by a formula.

$$C_{AC} \geq \frac{3T_D}{50\Omega}, T_D \text{ is the transmission line delay}$$

Typical value for C_{AC} is 60 pF, assuming delay of $T_D = 200 \text{ ps/inch}$ and 5 inch input clock route length.

Figure 23 DC coupled LVC MOS output clock configuration – configuration 2

Figure 24 DC coupled LVCMOS output clock with series RC termination – configuration 3

The typical value of R_{S1} and R_{S2} in this case is 1 KΩ and that of C_{AC} is 60 pF.

CMOS (Capacitive load)

The capacitive load can be driven as shown in Figure 25. $R_s = 33 \Omega$ for $VDDO = 3.3 V$.

Figure 25 Typical application load

Power Considerations

The following power consideration refers to the device-consumed power consumption only. The device power consumption is the sum of static power and dynamic power. The dynamic power usage consists of two components:
Power used by the device as it switches states

Power required to charge any output load. The output load can be capacitive-only or capacitive and resistive. Use the following formula to calculate the power consumption of the device:

$$P_{DEV} = P_{STATIC} + P_{DYNAMIC} + P_{CLOAD}$$

$$P_{STATIC} = I_{CORE_STATIC} * VDD + I_{ODR_STATIC} * VDDO$$

$$P_{DYNAMIC} = I_{CORE_DYNAMIC_100MHZ} * VDD * \frac{F_{in}(units\ in\ MHz)}{100} + C_{PD} * 5 * F_{in} * VDDO^2$$

$$P_{CLOAD} = C_{LOAD} * 5 * F_{in} * VDDO^2$$

Let us calculate typical power dissipation for C_{LOAD} of 2 pF at input clock of 100 MHz. Assume that $VDD = VDDO = 3.3 V$.

$$P_{STATIC} = 16mA * 3.3V + 3.5mA * 3.3V = 64.35mW$$

$$P_{DYNAMIC} = 1.5mA * \frac{100}{100} * 3.3V + 4.0pF * 5 * 100MHz * 3.3V * 3.3V = 26.73 mW$$

$$P_{CLOAD} = 2pF * 5 * 100MHz * 3.3V * 3.3V = 10.89mW$$

$$P_{DEV} = 102m$$

Core Current in XO Mode

The crystal mode standalone block current is measured in ATE. We can calculate total VDD core current in crystal mode, in typical condition using the below equation. The worst case VDD core current will be 14 mA, in crystal mode.

$$I_{core_crystal} = 8.5 + I_{xo_standalone} = 11.5mA, typical$$

Parameter Measurement Information

Differential Input Level

The parameter definitions related to differential input level is shown in [Figure 26](#).

Hot Swap Recommendations

Introduction

Hot-swap is a term used to refer to the insertion and removal of a daughter card from a backplane without powering down the system power. With today's high speed data and redundancy requirements, many systems are required to run continuously without being powered down. If special considerations are not taken, the device can be damaged.

Typical Differential Input Clock

For example, Figure 29 shows a typical LVPECL driver and differential input. If the power of the driver (VDDO) is turned on before the input supply (VDDI), there is a possibility that the input current could exceed the limit and damage diode D1.

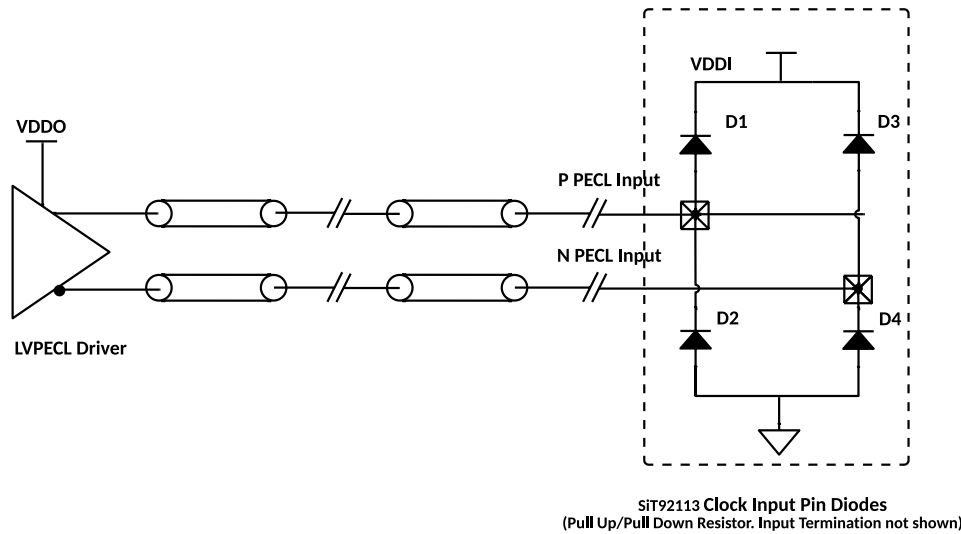

Figure 29 Typical input differential clock

To ensure the input current does not exceed its limit and damage the device, a current limiting resistor can be used. Below are examples of the most common termination topologies using a series current limiting resistor. Though it's not necessary, but if board space allows, some of the examples have an optional 100pf capacitor which assists with the integrity of the rise time. It is also recommended that the current limiting resistor be as close to the receiver as possible

LVCMOS Input Clock and Power Supply Sequencing

Figure 35 shows LVCMOS applications driving the input clock of SiT92113 without a 50 Ω load termination, which present a purely capacitive load to the LVCMOS driver.

Figure 35 LVCMOS Input Clock without 50 Ω Load Termination

For the applications shown in Figure 35, LVCMOS input clock to the SiT92113 buffer should come after the power

supply ramp. Figure 36 shows the timing requirement of Input Clock start versus VDD ramp.

Figure 36 LVCOMS Input clock to VDD ramp timing requirement for SiT92113

Operation in Multiple V_{DDO} Supply Domains

The V_{DDO} pins, 2 and 6 on the left side are shorted internally. These pins along with ODR CLK_{OUT}0 to CLK_{OUT}1 belong to a single supply domain. The V_{DDO} pins, 18 and 14 on the left side are shorted internally. These pins along with ODR CLK_{OUT}2 to CLK_{OUT}4 belong to a single supply domain.

These two supply domains are totally independent of each other. Pin 2, 6 can be connected to say 3.3 V while pin 18, 14 can be connected to 1.8 V. In this example, CLK_{OUT}0 to CLK_{OUT}1 will be 3.3 V LVCMOS driver. CLK_{OUT}2 to CLK_{OUT}4 will be 1.8 V LVCMOS driver.

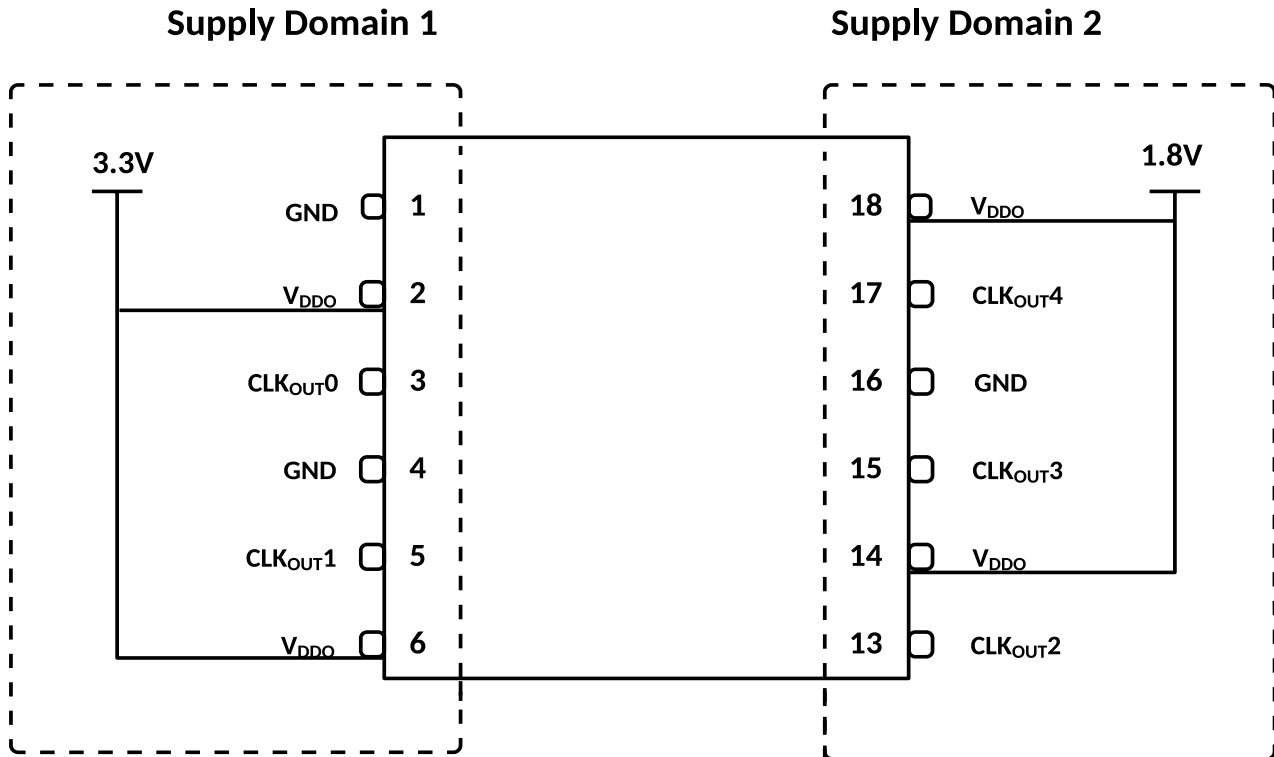

Figure 37 Example of multi supply operation of SiT92113

Note:

1. Supply Domain 1 and Supply Domain 2 are independent of each other.
